

Mobilizing Money through Enabling Regulation

Money will be fully mobile only when everyone has a safe place to store it, and the capability to receive and make payments, quickly and affordably, from and to any other person or entity from that store of value—in other words, to use mobile money.¹ We are a long way from that goal today. Bank accounts are regarded as the traditional safe place to store money, yet a 2006 study estimated that globally perhaps only 1.5 billion people have bank accounts.² Not all of these accounts have the level of speed or convenience—mobility—that comes from electronic banking, although the usage of e-banking channels has grown with the issuance of ATM and debit cards over the past two decades: in some developing countries, people still have passbook-based or domiciled accounts in which their money is effectively immobilized to cash access at one branch.

At the same time, we have witnessed the amazing rates of adoption of mobile phone communications even in the poorest and most remote countries: in 2009, by far the majority of the earth's population will live in areas with wireless reception, and four billion people will be mobile subscribers, most of them prepaid. Even if we account for the double counting that occurs because of multiple mobile subscriptions,³ it is clear that many more people are now in real-time voice or SMS contact with others across the globe, compared to the numbers using electronic financial services.

What would it take to mobilize money fully? First, people need easy and affordable universal access to wireless telephony. This is not yet available: even though subscriber bases continue to grow rapidly in many developing countries, that growth may be limited by income, topography and market structure. However, the limits to mobile penetration are clearly not the binding constraint on

David Porteous is Founder and Director of Bankable Frontier Associates, a consulting firm based in Boston, Massachusetts. The author wishes to thank the UK's Department for International Development (DFID), which financed BFA involvement in several projects that lead to some of the conclusions in this article; and CGAP, the Consultative Group to Assist the Poor (especially Tim Lyman, Gautam Ivatury and Mark Pickens), with whom Porteous has worked directly or in collaboration on many of the issues in this paper over the last three years.

the growth of mobile money at present. Second, providers must have robust business models that give them incentives to provide small-value financial services, even to low-income people who have never before used banks. This is where the transformational potential of mobile money lies: enabling hundreds of millions, even billions, of new clients to use appropriate formal financial services. If mobile money were only another channel for the already banked customer, it would be much less transformational.

The good news is that across different parts of the world a range of providers—banks, microfinance entities, mobile network operators, and third-party payment providers—have been actively experimenting with new business models for mobile money. Many are still at an early stage, so we do not yet know all the characteristics of the models that will prove successful over time. Some are beyond this early stage: the incredibly rapid adoption of Safaricom's M-Pesa's mobile money transfer service in Kenya has set new records and raised expectations about what is possible. Meanwhile, the early pioneers of mobile money in countries like the Philippines and South Africa are maturing and evolving as they learn more about what works and what doesn't.

The level of interest in mobile money is now strong enough to ensure that new business models will still emerge and some, though not all, of the existing models will evolve and become robust. However, both the providers and close observers of the sector agree that inappropriate regulation constrains the development of transformational mobile money models in many places.⁴ Or to put this another way, an enabling policy and regulatory environment is vital if transformational branchless banking is to emerge and develop. This was the key argument of an early report BFA (2006) wrote for Britain's Department for International Development (DFID) almost three years ago. Three years later, much more research has been done to understand the regulatory issues affecting mobile money across a number of countries, much of it undertaken or supported by CGAP (the Consultative Group to Assist the Poor) and DFID.⁵ We have come to understand much better how to diagnose the regulatory environment for mobile money in a country, and consequently how to identify and recommend the necessary changes.

Indeed, we are now in a position to test a hypothesis that is implicit in the statement above: if regulation is indeed a key constraint on the development of mobile money models, then we would expect to see more activity and development in those jurisdictions that are more conducive to the emergence of these models, and less development in those that are not. The problem with testing this hypothesis has been how to rate the "conduciveness" of a regulatory environment on a consistent basis to facilitate the comparisons. Building on the general approach we proposed in 2006, in this article I develop a rating system that provides a basis for comparison across countries and describes the initial results from four countries with active mobile money models. These results confirm the hypothesis: having an enabling environment matters for the emergence and development of mobile money. The rating approach also provides a basis on which countries can be encouraged and supported to make moves in this direction.

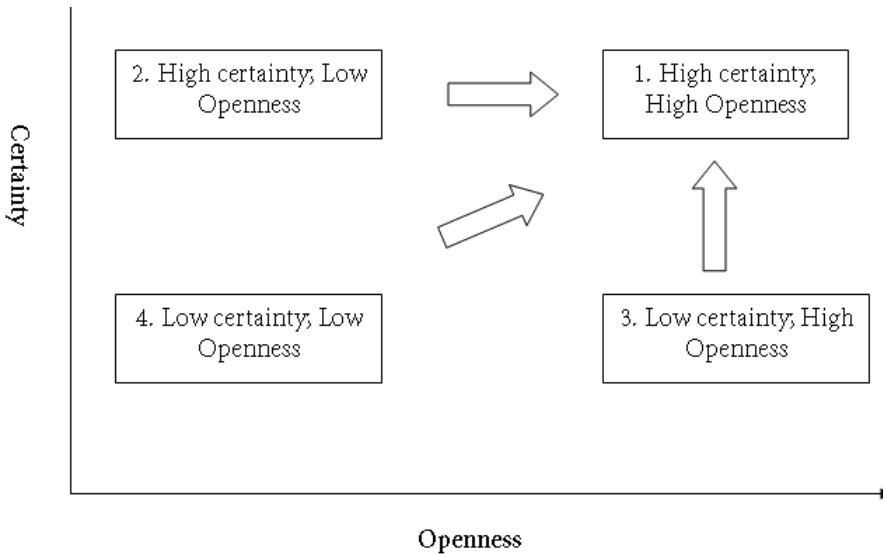

Figure 1. Dimensions of an Enabling Environment. Source: Based on BFA 2006.

WHAT IS AN ENABLING ENVIRONMENT FOR MOBILE MONEY?

An enabling environment is one that allows, and may even encourage, the introduction and development of new business models that meet a defined public policy objective. In this case, the objective espoused by many countries is that of increasing financial inclusion—that is, the proportion of people with appropriate formal financial services. In our 2006 report for DFID, we proposed two key dimensions for an enabling environment in a new sector like mobile money. These were:

Openness: the extent to which new models that had the potential to be transformational were not prohibited from starting up.

Certainty: the extent to which policymakers and regulators provide clarity that reduces the level of risk for private sector operators, not only at startup but over time.

In that report, we depicted the possible combinations by placing each of these dimensions on one axis, as shown in Figure 1 (above). Dividing the space into high and low zones on each axis produces the four quadrants indicated.

Quadrant 1 (high certainty and high openness) is clearly the most suitable situation to facilitate mobile money, hence the direction of the arrows. However, based on early diagnostic work in two African countries (South Africa and Kenya), we hypothesized that middle-income countries like South Africa were more likely than low-income countries to be in quadrant 2 (high certainty, low openness) because they typically have more developed regulatory regimes. That is, they usually have a range of regulatory institutions that have issued regulations or guidance on mobile money or related issues, increasing the certainty, but they face the real

risk that a plethora of overlapping and sometimes obsolete regulations will reduce the space in which they can innovate. Conversely, we hypothesized that in low-income countries like Kenya, there was simply less on the books in the way of legislation and regulation, usually resulting in more discretion for regulators (and correspondingly, less certainty for providers), but this lack of regulation could also create more openness for the development of innovative models. The report suggested which regulatory domains were affected by mobile money but did little to prioritize among them.

Recently, Tim Lyman, Mark Pickens and I (2008) went further, suggesting how to prioritize the factors based on identifying two necessary conditions for branch-less banking to emerge from the range of country diagnostic missions undertaken in 2007. These conditions are:

Agents must be allowed to operate on behalf of banks and others to open accounts and handle cash-in and cash-out functions. As Lyman, Ivatury, and Staschen (2006) argued convincingly, this particular arrangement greatly extends the potential reach of the financial system, since existing businesses, such as local merchants, can function as financial service points at much lower cost than if a bank had to set up a new branch or even an ATM infrastructure.

Regimes to oppose money laundering and the financing of terrorism (AML-CFT) should be proportionate. Specifically, the due diligence procedures required under Know Your Customer (KYC) regulations (now present in most countries) for opening new deposit accounts or taking payments must allow for reduced identification and verification procedures for low-risk customers. Otherwise, low-income people could never meet the standards set in developed countries, which, for example, require them to verify a physical address by presenting a utility or other bill.

Lyman et al. (2006) identified four more regulatory areas (“next generation issues”) that would affect the trajectory of development. There should be an appropriate space to issue e-money and other stored value instruments, along with effective consumer protection, an inclusive system to regulate payments, and appropriate competition rules for new payment systems.

They also affirmed the earlier observation that, because the regulation of mobile money cuts across many regulatory domains, the risk of coordination failure is higher. Without the clear leadership and policy direction that will enable this space to develop, there is less prospect of necessary changes being coordinated across different regulatory agencies, or even across divisions within one agency, such as a central bank of a particular country. Lack of coordination among regulators remains one of the biggest obstacles to progress. Even if one agency is positive about the prospects for mobile money, and wants to enable it, changes in one area alone are often not sufficient to enable change. This situation is common, for example, among payment system supervisors who want to make their retail payment systems more efficient.

FROM INFORMATION TO RATING

Thanks to such research, we now have greater clarity about the balance of factors that are more likely to result in the emergence of transformational models for mobile money. However, it remains hard to compare the situation across countries based on qualitative information alone. The value of cross-country ratings in creating a focus on the underlying issues has been amply demonstrated in recent years by the World Bank's annual Doing Business Surveys. These surveys, now performed in some 181 countries, annually collect information that the World Bank then uses to populate a scorecard for each country across 11 components of the business environment. The resulting relative overall and sectoral scores can then be compared and analyzed in depth. The website, www.doingbusiness.org, provides tools to facilitate this comparison and analysis.

The success of a rating scale derives from the clarity of its purpose. For Doing Business, the scores seek in essence to measure the extent to which private sector development is possible and likely in a country. Our objective here is in some ways a specialized subset of this aim: we want to compare the extent to which transformational mobile money models of all forms are allowed and enabled across countries.

To proceed from the general insights about regulatory factors above to a country rating model for mobile money, we took two steps:⁶

We designed a simplified questionnaire that collects answers about the status of policy or legislation (including regulation or guidance) across the two dimensions of openness and certainty and in the main domains bearing on mobile money in a definitive “yes,” “no,” or “maybe” format. In general, the questions were designed to be factual and clear so that a “yes” answer was positive, and a “no” was negative. To produce clear results, a questionnaire like this has to sacrifice some of the underlying complexity. Part of this questionnaire appears in the Annex.

We then developed a scoring model that weights the answers obtained relative to the purpose of the rating expressed above: the weights we use for each of the eight domains are shown in Table 1. We used our judgment to develop the weighting, which clearly prioritizes the two necessary conditions described above (AML/CFT and use of agents, in items 2 and 4 below), as well as the environment for issuing e-money (item 3 below).

INITIAL RESULTS

There are different ways to collect the data necessary to populate the diagnostic questionnaire, as described in the Text Box titled “Collecting the Data.” Depending on the level of published material, the information can be difficult and expensive to obtain. Therefore, we focus here on using publicly available information from diagnostics in four key countries, chosen because of their scale and the levels of interest and activity in mobile banking. They include three leading countries that are mobile money pioneers in the developing world—Kenya, the Philippines, and

Collecting the Data

Because of the complexity introduced by the cross-cutting regulatory domains involved in mobile money, collecting accurate data can be time-consuming and expensive. At least three methodologies have been tried.

In-country mission. A team of skilled external experts, supported by local legal advisors, can meet with key regulators and market players to understand the environment in order to produce a comprehensive view. CGAP commissioned seven such diagnostic missions in 2007, resulting in country notes that are available at <http://www.cgap.org/p/site/c/template.rc/1.11.1772>. This approach is certainly likely to result in the best quality of information, but requires having a skilled mission team in-country for up to ten days, making the process expensive and time-consuming.

Desk review. Researchers can review available published information, even using the local resources in a country. We tried this approach as part of the Mobile Money Transfer Project, which involved cooperation between CGAP, DFID and GSMA in 2006 and 2007. We found, first, that it is not easy for a local person to make sense of what is sometimes a thicket of laws, regulations, and guidance. Second, the easy availability of published regulations or guidelines declines steeply with a country's level of income. That is, researchers can be overwhelmed by the task of collating the available information for say, the UK; meanwhile they find that for most low-income countries, little is publicly available. Hence, they need to engage with policymakers and regulators to get a sense of their intentions and attitudes.

Self diagnostic. Regulators themselves can be asked to complete a diagnostic questionnaire, on the assumption that they are best placed to answer the questions authoritatively. We designed what we call a "diagnostic lite" questionnaire for the payment regulators of the 15 Southern African Development Community (SADC) countries in a 2007 DFID-funded project. This is an improvement on the desk review approach because the regulator is directly involved. However, the underlying issues in the questionnaire cut across regulatory boundaries, making it hard for one agency or one division within an agency (such as the Payment Systems Divisions) to complete all the aspects of a diagnostic with equivalent levels of knowledge or certainty.

In the results reported here, we draw on published information that relies on data we collected in 2007 for the four countries, using the methodologies described above, to reach our own answers to the questions in the diagnostic lite.

South Africa—and India. In India, interest in mobile money has exploded in the past three years, after mobile subscriptions took off in that massive country with its great infrastructural challenges for traditional models of extending the financial system. Several Indian banks have introduced various mobile channels for their customers, although mass usage of those channels reportedly remains low and is

	Openness	Certainty
1. E-commerce	5%	10%
2. AML/CFT	25%	10%
3. Electronic stores of value	25%	25%
4. Outsourcing and use of agents	30%	20%
5. Consumer protection	5%	20%
6. Foreign exchange control	5%	NA
7. Taxation of financial services transactions	5%	NA
8. Coordination	NA	15%
TOTAL	100%	100%

Table 1. Weighting of domains in the scorecard.

certainly not yet transformational. Meanwhile, other service providers (third party and mobile network operators) have been developing plans to enter the space. While this is a small sample, these four countries offer sufficient variation in terms of income level per capita and extent of activity and development in mobile money to test our hypotheses about enabling environments and the growth of mobile money.

Figure 2 plots the scores we obtained for each of the four countries when we applied the rating to the diagnostic questionnaire on each of the two dimensions. The space is divided into four quadrants using median scores on each axis for six countries.⁷ Clearly only the relative scores have meaning.

The outcome of the scoring summarized in Figure 2 supports several of the hypotheses I advanced earlier. Three points are especially important. First, the openness of the environment does indeed matter: in all of the three countries that are ranked much higher on the openness axis (i.e. to the right-hand side), mobile money models have been relatively more active for longer and are more widely used, compared to India, which lies lower on the openness axis.

Second, however, the countries classified as middle income by the World Bank (South Africa, the Philippines, and India) all lie higher on the certainty scale than low-income Kenya, which is clearly in the bottom right quadrant (high openness but low certainty). The Philippines is positioned just inside the top right quadrant, reflecting the fact that while its environment is very open, some of the models have been authorized based on bilateral letters of agreement, although the Central Bank of the Philippines is now seeking to move beyond this level of discretion toward a

	GNI per capita (\$ current, 2007)	Country classification	% mobile penetration	% banked	Estimated number of mobile money users
India	\$950	Lower middle	21%	48%	Not known
Kenya	\$680	Low income	30%	10%/19%	4m
Philippines	\$1620	Lower middle	50%	26%	2.5m
South Africa	\$5760	Upper middle	89%	46%/51%	4m

Table 2. Comparing the sample countries.

Sources: World Development Indicators, World Bank, Honohan (2007), Finscope, and local sources.

Specific sources of data are as follows.

- GNI per capita is from World Development Indicators (WDI) for 2007.
- Country classifications are from the World Bank website.
- Mobile penetration is from WDI 2007, section on mobile penetration.
- Percentage banked is from Honohan (2007); that for Kenya and South Africa comes from FinScope household survey data for 2006 and 2007 respectively (see <http://www.finscope.co.za/southafrica.html>. For background and publications from FinScope SA and <http://www.fsdkenya.org/finaccess/index.html> for Kenya).
- Estimates of number of mobile money users were compiled from a range of local sources: in Kenya, registered M-Pesa subscribers reported as of October 2008, which understates the number since there are other but much smaller m-banking services available; in South Africa, press reports in September, 2008; in the Philippines, aggregates of active customer numbers of G-Cash and SmartMoney in 2008.

broader framework in key areas like e-money issuance by non-banks. In some ways, South Africa's position is surprising: experiments began there comparatively early and several well-known pioneering models such as Wizzit and MTN Mobile Money emanate from there, but the role that non-banks can play in issuing e-money is circumscribed by the current guidance note on e-money, which has frustrated some potential innovators. To further enhance its environment, South Africa would have to amend its position, for example, by creating a category of regulation for non-bank e-money issuers, or "narrow banks," a step that has in fact been considered. In general, common law countries have an advantage in terms of openness because of the presumption that whatever is not prohibited is in fact allowed; in civil law countries, the reverse applies.⁸

Finally, India has a plethora of legislation. Its laws, regulations, and guidelines across a range of areas provide certainty, but limit the openness on key issues; for example, what types of entities can serve as agents? The Reserve Bank of India first allowed agents to function in 2006, and in 2008 issued further guidelines to clari-

Figure 2. Rating scores.

Source: BFA scoring methodology based on information for each country obtained in 2007.

fy the restrictions on this role.

While it is easy to make the case for openness, recent events in Kenya also show the importance of certainty. For example, M-Pesa, perhaps the largest single mobile money model in these four countries based on number of users, is not formally regulated but operates at a system-wide scale under a no-objection letter from Kenya's Central Bank. The bank has expressed its intention to introduce the necessary laws and regulations to bring greater certainty, but as recently as December 2008, the minister of finance called for a special audit, announcing concerns over the fact that M-Pesa is unregulated.⁹

Clearly, openness and certainty alone are not sufficient to ensure the sustainable development of mobile money. The safety of clients' deposits matters too, as Lyman, Pickens, and Porteous (2008) point out. In the absence of a framework that creates certainty about which types of entities can enter and how they must behave, too much openness to innovative models from new entrants can be risky, especially once these models move beyond the small-scale pilot stages. In 2006, BFA argued for a phased approach that is more open to a range of models at early stages of market development but then introduces successively increasing certainty, together with client safeguards, as the market scales up. To date, the Philippines is probably the best country example of this phasing. But the speed at which Kenyans have adopted M-Pesa should wake up regulators who think they can postpone a response to mobile money: appropriate models can scale up very quickly, and policymakers and regulators must explicitly consider this possibility in advance so that they have prepared their options to ratchet up their responses over

time.

IMPLICATIONS AND CONCLUSIONS

I have described a simple method for rating country environments for mobile money. By demonstrating the results of our scoring for four developing countries that lie at the heart of much activity in mobile money, I have shown how the methodology appears quite robust in locating the countries, compared to earlier expectations. Clearly, the scoring model would benefit from being extended to include data from other countries in order to broaden the sample and define the medians of openness and certainty based on more variety. In fact, we have already applied the methodology to an additional four countries, as well as to the ten SADC countries other than South Africa that completed self-diagnostic questionnaires in late 2007, but we cannot yet publish these results.¹⁰ But this extension would allow us to further refine our questions and weightings.

For now, the rating methodology offers a promising means to compare countries in a simple but clear way. This has clear implications for each of two main sets of users.

First, for international mobile money providers looking to enter new markets, this rating system is a relatively low-cost tool to screen for (or at least understand) a choice of country in terms of some of the most vital regulatory issues that can so hamper or facilitate subsequent development.

Second, for policymakers and regulators, this methodology, like other country ratings, should stimulate pointed discussions about how to facilitate the development of mobile money. The answers to the underlying diagnostic questions provide a way for regulators to assess their own situation and to consider what they can do. Whether or not policymakers are concerned about their country's relative ranking on any rating, they should be concerned about improving their enabling environment for mobile money. High-level policymakers can take an important first step by creating a task force across the involved regulatory agencies. This task force should have the mandate of preparing a road map that shows how the necessary enabling changes can be sequenced and coordinated, proportionately to the level of market development. If most regulators took this approach, then money would indeed begin to be fully mobilized.

Endnotes

1. Following the definition set out, for example, by Beth Jenkins (2008) in *Developing Mobile Money Ecosystems* (available via <<http://www2.cgap.org/gm/document-1.9.4914/GSMA%20Mobile%20Money%20Summit%20MMT%20Cairo%202008.pdf>>), we use the term mobile money to refer to models of financial service provision involving mobile phones, including both m-banking and m-payments.
2. Littlefield, Helms and Porteous. (2006). "Financial Inclusion 2015: Four scenarios for the future of microfinance," *Focus Note No. 39*, available at <http://www.cgap.org/p/site/c/template.rc/1.9.2579>.
3. The mobile industry counts numbers of subscriptions to determine the number of users. Though banking uses no single approach, we advocate counting the number of individuals with bank

accounts, not the number of accounts as some surveys have done, since individuals are likely to have multiple bank accounts. From analyzing data from national surveys in Africa, we learned that the number of subscribers per individual with a mobile varies from 2 in more developed markets like South Africa to 1.2 in Kenya. See BFA (2007), Table 15 and surrounding. Ewan Sutherland (2008) provides a useful note in Counting mobile telephones, SIM cards and customers, a report for the LINK Center available at http://www.researchictafrica.net/images/upload/Mobile%20numbers_Ewan.pdf. He suggests that the number of people who have phones may as low as one sixth of the number who have subscriptions.

4. To give just one recent example, in a poll of 30 experts at a CGAP-MicroSave workshop held in August 2008, including representatives of some of the pioneers of mobile money, almost 80% agreed or strongly agreed that “regulatory constraints are restraining the growth of m-banking solutions.”
5. More recently, the Asian Development Bank and the Inter-Asian Development Bank, among others, have done similar research.
6. We first did this in a DFID-financed report for 15 SADC countries using responses from each central bank to questionnaires, although the country-specific results have not yet been published and hence are not used here.
7. The other two countries are middle-income Mexico, and lower-income Papua New Guinea. They broaden the sample medians, although we do not specifically report on them here.
8. Indeed, this is our experience of rating two unnamed civil-code countries: one (a LIC) falls into the bottom left corner, the lowest potential quadrant. This is of course in line with the general findings of doing business that common law environments are usually more enabling for business than civil-code countries.
9. *Business Daily*, 10 December 2008, page 1, available at http://www.bdafrica.com/index.php?option=com_content&task=view&id=11685&Itemid=5812
10. We are cooperating with the Spanish consulting firm AFI to rate six Latin American countries at different stages of development, and expect the results after the first quarter of 2009.

ANNEX.
DIAGNOSTIC SELF-ASSESSMENT QUESTIONNAIRE

B. OPENNESS

B1 E-commerce

B1.1

Question: Are electronic signatures (e.g. PIN numbers to authorize transactions) widely accepted in practice for financial transactions?

Why does this matter? If PINs are already widely used and accepted, then the lack of an e-signature law may not stop initial developments to e-payments.

B2. AML/CFT

B2.1.

Question: Is there provision for lighter CDD procedures for those opening low-value bank accounts or making low-value payments?

Why does this matter? Unless CDD procedures are appropriate to the risks and situation of the unbanked, they may rule out any transformational approaches.

B2.2

Question: Is the remote opening of bank accounts allowed (i.e. outside of bank premises and/or by agents of bank)?

Why does this matter? For reasons of cost and perception, regimes that explicitly allow accounts to be opened outside bank branches are more likely to be transformational.

B3. Electronic stores of value

B3.1

Question: Are pre-paid cards allowed that can be used at multiple sites other than the issuer?

Why does this matter? Pre-paid cards or instruments that can be used other than to buy the goods and services of the issuer are already a form of e-money.

B3.2

Question: Are non-banks allowed to offer and operate general use pre-paid stores of value (whether accessed by card or other instrument such as mobile phone)?

B3.3

Question: Are telephone companies able to provide services (such as ringtones or information) to mobile phone users for which they may pay from their pre-paid accounts?

Why does this matter? In some circumstances, this may already constitute the use of e-money.

B4. Outsourcing and use of agents

B4.1

Question: Are agents allowed to open new accounts on behalf of banks?

Why does this matter? Agents may offer another lower-cost distribution channel for opening accounts.

B4.2

Question: Are agents allowed to handle cash-in/cash-out transactions on behalf of Banks?

Why does this matter? Agents may offer another lower-cost distribution channel for withdrawals and deposits from bank accounts.

B4.3

Question: Are agents allowed to handle cash-in/cash-out transactions on behalf of non-banks that operate payment services/store of value?

Why does this matter? Agents may offer another lower-cost distribution channel for withdrawals and deposits from these stores.

If answer to B4.2 or B4.3 above is yes, do the legal requirements for doing so allow a wide range of types and sizes of agent?

B4.4

Question: Are banks allowed to outsource the maintenance of account-level account management to third parties?

Why does this matter? Outsourcing may provide cheaper models.

B4.5

Question: Are banks allowed to co-brand or offer their banking products under brand names different from their own?

Why does this matter? Variable branding may increase the reach of products.

B5. Consumer protection

B5.1.

Question: Is there a requirement that paper statements be mailed on a regular basis to holders of bank accounts/stores of value?

Why does this matter? Disclosure requirements will affect the cost and flexibility of new offerings.

B6. Foreign exchange control

B6.1

Question: Are there foreign exchange controls that apply to either incoming or outgoing international remittances by individuals of low value?

Why does this matter? Foreign exchange controls affect the cost and process involved with foreign remittances.

B7. Taxation of financial transactions

B7.1

Question: Are transactions involving a transfer of monetary value treated the same whether the transfer service is provided by a bank or by a non-bank?

Why does this matter? Differential taxation by sector will affect whether it is viable to offer payment services.

C. CERTAINTY

C1. E-commerce

C1.1

Question: Is there legislation in effect that provides for the validity of electronic signatures?

Why does this matter? This provides certainty of legal treatment for electronically authorized transactions, which is necessary for scale usage.

C2. AML/CFT

C2.1

Question: Are the AML/CFT exemptions codified in regulations or official guidance?

Why does this matter? A clear AML/CFT regime will not leave providers exposed to undue uncertainty as to how to apply the laws.

C2.2

Question: Is the provision for remote account opening codified in regulation or official guidance?

C3. Electronic stores of value

C3.1

Question: Is there a clear legal definition of “payment”?

Why does this matter? While a deposit is usually defined in the main banking law, certainty requires a clear distinction between a payment and a deposit.

C3.2

Question: Is there a law governing the provision of payment services?

Why does this matter? This follows from 3.1, to cover the activities of those in the business of offering payment services

C3.3

Question: Is there a clear legal or official definition of “e-money”?

Why does this matter? E-money takes various forms, and an official definition, whether in policy or law, will help to provide clarity.

C3.4

Question: Is there a defined law or policy stating which entities may issue e-money?

Why does this matter? This follows from C3.3 and provides clarity on how e-money may be issued.

C4. Outsourcing and use of agents

C4.1

Question: Are there regulations that specify which services banks can outsource?

Why does this matter? Outsourcing regulations provide a framework within which to consider what may be outsourced and on what terms.

C4.2

Question: Are there regulations that govern the banks’ appointment of banking agents/correspondents?

Why does this matter? Specific regulations may be required to provide certainty as to the obligations of agents and principals in this relationship.

C5. Consumer protection

C5.1

Question: Are there any particular consumer protection laws, regulations or codes that apply to the provision of bank accounts or payments services?

Why does this matter? This will provide clarity about what the obligations of the service provider may be, and about the risks to which the customer may be exposed.

C5.2

Question: Are there laws or regulations that specifically govern electronic transactions by retail customers?

Why does this matter? Electronic transactions bring new risks, and specific regulations may be required to provide certainty and standardization in how they are addressed.

If so, do they specify the following:

C5.3

Customer liability for unauthorized transactions.

Why does this matter? The liability should clearly rest on one party, usually the provider.

C5.4

Dispute resolution procedures.

Why does this matter? It is often necessary to specify channels other than the courts for fast, cost-effective resolution of consumer grievances.

C6. Coordination

C6.1

Question: Does the country have a policy paper or discussion paper setting out policy towards m-payments or m-banking?

Why does this matter? This should increase certainty by indicating the questions and issues that concern policy makers, even if it does not provide answers.

C6.2

Question: Has a lead regulator for m-banking and m-payments been clearly identified?

Why does this matter? Having one agency able to provide regulatory leadership may increase certainty, and reduce risk of coordination failure.

C6.3

Question: Has a policy-making ministry for m-banking and m-payments been clearly identified?

Why does this matter? Having one ministry responsible for producing policy is likely to increase certainty and reduce risk of coordination failure.

C6.4

Question: Have regulators and policy makers from different agencies whose domains are affected met to discuss policy coordination around m-payments and m-banking?

Why does this matter? Even meeting together can improve coordination and increase certainty.
